

PdfttDown comes with a command line application from which you can comfortably convert all your files without actually touching a single line of code.

Based on [click](#), the CLI is designed to offer a seamless experience, with almost as much control of inputs and outputs as if you were to write the flow in python: it is then the perfect choice if you want an easy and intuitive approach to file conversion, without getting your hands dirty with code.

Usage

Below are some example commands for using PdfttDown from the terminal, along with explanations for each option and scenario:

Convert a single file to PDF

Use this command to convert a single file (e.g., a Markdown file) to PDF and set a custom title in the PDF metadata:

```
pdffitdown -i README.md -o README.pdf -t "README"
```

- `-i README.md`: Specifies the input file to convert.
- `-o README.pdf`: Sets the output PDF file path.
- `-t "README"`: Sets the PDF title metadata.

Convert multiple files with custom output paths

You can convert several files at once, specifying a matching output PDF for each input:

```
pdffitdown -i test0.png -i test1.md -o testoutput0.pdf -o testoutput1.pdf
```

- Multiple `-i` flags: List each input file you want to convert.
- Multiple `-o` flags: Provide an output path for each input file, in the same order.

Convert multiple files with inferred output paths

If you omit the output file paths, PdfttDown will automatically generate PDF filenames based on your input files:

```
pdffitdown -i test0.png -i test1.csv
```

- Output files will be named after the input files, with `.pdf` extensions.

Bulk convert all files in a directory

To convert every file in a directory to PDF in one go:

```
pdffitdown -d tests/data/testdir
```

- `-d tests/data/testdir`: Specifies the directory containing files to convert. All supported files in this directory will be converted to PDF.

For more details on available options, run:

```
pdfitdown --help
```
